# Plano de Aula

- Discussões Iniciais
- Classificação Binária vs Multi-classe
- SVM
- Exercícios

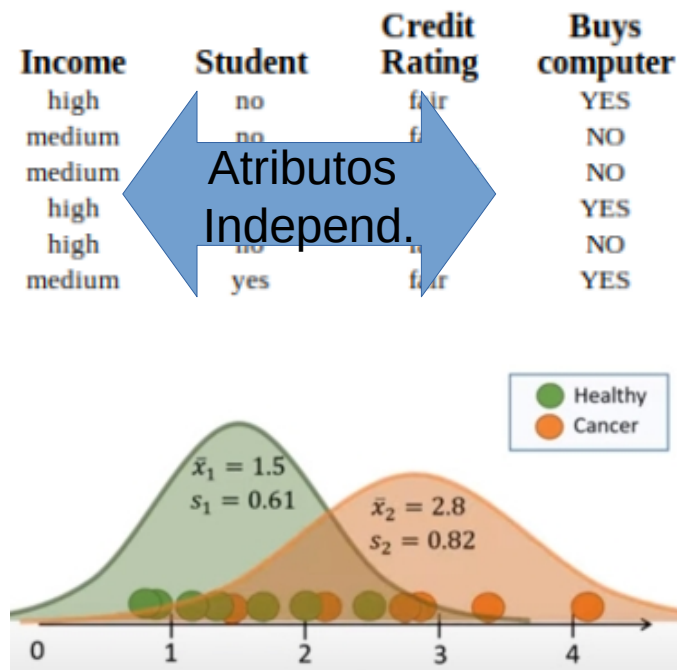

# Discussões Iniciais

- KNN

Naive Bayes

Decision Tree

- Classificação Multi-Classes é implícita

# Classificação Binária vs Multi-Classes

- Os modelos vistos até agora, trabalham implicitamente com problemas multi-classes exclusivamente pela natureza de seus algoritmos
  - Vizinhaça
  - Probabilísticos

# Classificação Binária vs Multi-Classes

- Mas e quando o modelo é naturalmente binário?
  - SVM
  - RNA

# Classificação Binária vs Multi-Classes

- One-vs-All (OVA) ou One-vs-Rest (OVR)
  - Modelo 1:- [Green] vs [Red, Blue]
  - Modelo 2:- [Blue] vs [Green, Red]
  - Modelo 3:- [Red] vs [Blue, Green]
- Predict:  $\text{Max}(\text{Modelo 1}, \text{Modelo 2}, \text{Modelo 3})$

**One-vs-all (one-vs-rest):**

Class 1: Green  
Class 2: Blue  
Class 3: Red

# Classificação Binária vs Multi-Classes

- One-vs-One
  - Número de Modelos:  $N * (N-1) / 2$

**One-vs-One**

Class 1: Green  
Class 2: Blue  
Class 3: Red

# SVM Linear

- Vladimir Vapnik (1979)
- Binário – Não Probabilístico
- Define um hiperplano de separação das classes
  - +1 e -1
- Parâmetros: C (Regularização) e Kernel.

# SVM Linear

- Qual o melhor Hiperplano ?

# SVM Linear

- Definição da Margem

# SVM Linear

- Definição da Margem

- $f(x) = w \cdot x + b$ 
  - $w$  = pesos
  - $x$  = Amostras
  - $b$  = bias

- Logo  $y(x) =$

$$y(x) = \begin{cases} +1, & \text{se } wx + b > 0 \\ -1, & \text{se } wx + b < 0 \end{cases}$$

# SVM Linear

- Treinamento: Otimizar 'W' e 'b'

$$\begin{aligned} wx_a + b &= +1 \\ wx_b + b &= -1 \end{aligned} \Rightarrow w(x_a - x_b) = 2$$

$$w(x_a - x_b) = 2 \Rightarrow \|x_a - x_b\| = \frac{2}{\|w\|}$$

$$margem = \frac{2}{\|w\|} \Rightarrow \frac{1}{2} \|w\|^2$$

- Tem-se então a otimização de uma função quadrática, dada a restrição:

$$y_i(w \cdot x_i + b) \geq 1, i = 1, \dots, n$$

$x_i, i = 1, \dots, n$ , conjunto de padrões

$y_i = \{-1, +1\}, i = 1, \dots, n$ , respectivas classes

Lagrange

$$L(w, b, \alpha) = \frac{1}{2} \|w\|^2 - \sum_{i=1}^n \alpha_i (y_i (w x_i + b) - 1)$$

# SVM Linear (Margens Suaves)

- Presença de ruídos ou outliers
- Solução: Suavização (Folga)
  - C: Define a folga (Definido experimentalmente)

$$\frac{1}{2} \|w\|^2 + C \sum_{i=1}^n \xi_i$$

$$y_i(w x_i + b) \geq 1 - \xi_i$$

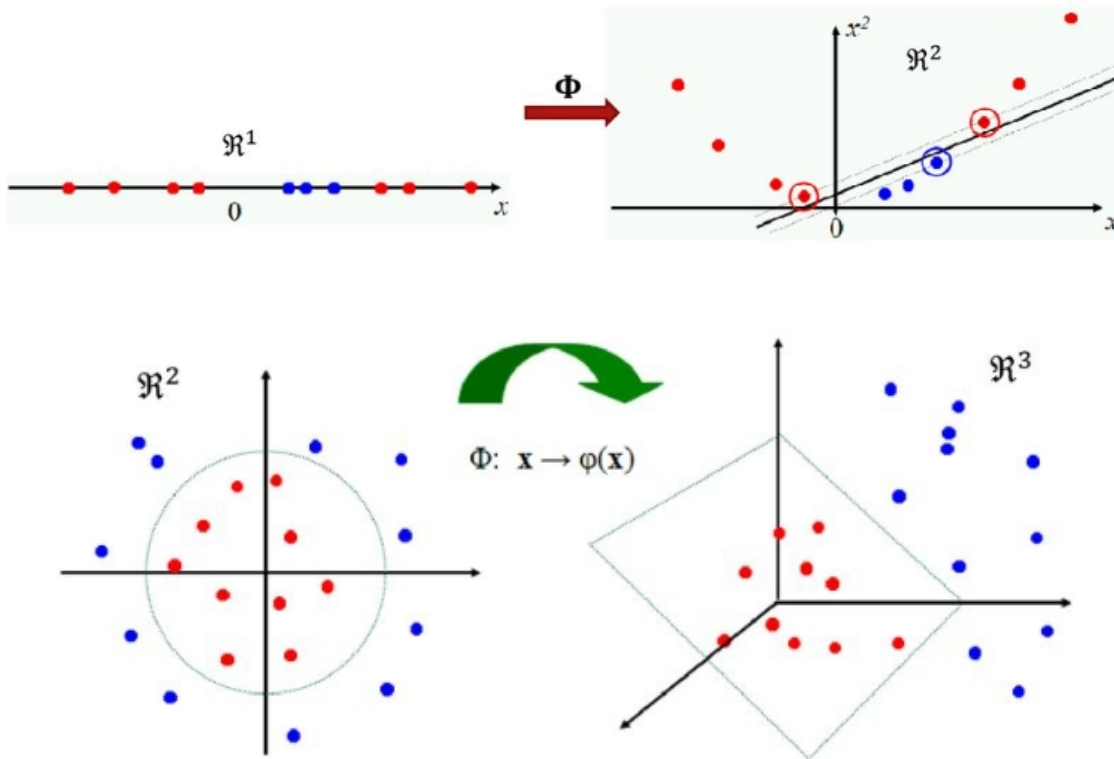

# SVM Não Linear

- E quando os dados não são linearmente separáveis?

# SVM Não Linear

- Encontrar uma transformação não linear ( $\Phi$ ) tal que  $\mathbb{R}^N \rightarrow \mathbb{R}^M$  ( $M > N$ )
  - Teorema de Cover

$$\frac{1}{2} \|w\|^2 + C \sum \xi_i$$

$$y_i(w \cdot \Phi(x_i) + b) \geq 1 - \xi_i, \forall x_i$$
$$\xi_i \geq 0$$

# SVM Não Linear

- Kernel Linear

linear kernel

- Non-Linear Kernels

- Polinomiais

$$(\delta(x_i \cdot x_j) + k)^d$$

polynomial kernel

- Gaussianos ou RBF

$$\exp(-\sigma \cdot \|x_i - x_j\|^2)$$

RBF kernel

# Considerações Finais

- Vantagens
  - Se adaptam bem a problemas complexos
  - Pouca parametrização ('C')
- Desvantagens
  - Otimização pode ser demasiadamente complexa
    - 'w', 'b' e Kernel podem demorar a convergir
    - Bases Volumosas ou Muitas Classes
  - Modelo Caixa-preta (Interpretabilidade reduzida)
